## Quick-Hit Newton's Law Problems 1 - KEY

- If the acceleration of a body is zero, are forces acting on it?  
**Acceleration of zero means that the *net* force is zero, not that there are *no* forces.**
- Why do you push harder on the pedals of a bicycle when first starting out than when moving at a constant speed? There are two reasons.  
**In order to accelerate from rest, the net force must be greater than zero. When moving at a constant speed, net force equals zero. When first starting to move, it is necessary to overcome static friction which is larger than kinetic friction.**
- When a golf ball is dropped on the pavement, it bounces back up. (A) Is a force need to make it bounce back up? (B) If so, what exerts the force? (C) How does this force compare to the golf ball's weight?  
**Yes, the ground exerts a force larger than the weight of the ball to give it a net upward force.**
- Why might your foot hurt if you kick a heavy desk or a wall? Explain using the appropriate Newtonian Law.  
**When you exert a force on an object, Newton's Third Law tells us that it exerts the same force back on you. Since your foot is much less massive than a heavy desk or wall, Newton's Second Law tells us that the acceleration of your foot is much larger than that of the desk or wall.**
- The force of gravity on a 2-kilogram rock is twice as great as that on a 1 kilogram rock. Why then doesn't the heavier rock fall faster?  
**Acceleration is proportional to force and inversely proportional to mass.  
 $F_w = -mg$  (up as positive).  $F = ma$ . So  $-mg = ma$ ,  $-g = a$  for both objects.**
- According to Newton's third law, each team in a tug of war pulls with equal force on the other team. What, then, determines which team will win?  
**Friction force. The team with more friction with the surface will win.**
- Sketch the free-body diagram of a softball (A) at the moment it is hit by the bat, and again (B) after it has left the bat and is flying towards the outfield.

- If the coefficient of kinetic friction between a 35-kilogram crate and the floor is 0.30, what horizontal force is required to move the crate at a steady speed across the floor? What horizontal force is required if  $\mu_k$  is zero?  
**105 N, 0 N**
- A cup of coffee on the dashboard of a car slides forward on the dash when the driver accelerates from 40 km/h to rest in 3.5 seconds or less, but not if she accelerates in a longer time. What is the coefficient of static friction between the cup and the dash?  
 **$a_{max} = 40 \text{ kph}/3.5\text{s} = 3.2 \text{ m/s}^2$ , (y)  $F_N = F_w = mg$ , (x)  $F_f = ma = \mu F_N \rightarrow \mu = a/g = 0.32$**

Review Problems (Challenging)

1. The system pictured below is in equilibrium, but begins to slip if any additional mass is added to the 5.0-kg object. What is the coefficient of static friction between the 10-kg block and the plane on which it rests?

$\mu = 0.375$

2. The system below is in equilibrium with the string in the center “exactly” horizontal. Find the angle  $\theta$  and the tension in each string. (Hint: Do 2 free body diagrams, one at each knot.)

$T_1 = 50 \text{ N}$   
 $T_2 = 30 \text{ N}$   
 $T_3 = 58.3 \text{ N}$   
 $\theta = 31^\circ$

3. The force,  $F$ , is just sufficient to hold the 14-N block and weightless pulleys in equilibrium. There is no appreciable friction between the cables and pulleys. Calculate the tension,  $T$ , in the upper cable

$T = 16 \text{ N}$
